

Transgenic grains again scare Europe after misleading GM study

The debate about the possible harmful effects of GM foods came roaring back after a French scientific research linked the appearance of cancerous tumors in rats consuming GM corn. The study caused an uproar and the French Prime Minister, Jean-Marc Ayrault, came to announce incentive measures for banning GMOs (genetically modified organisms) in all of Europe, if it confirms the result of the harmfulness of the product.

In research published in the journal Food and Chemical Toxicology, 200 rats were fed for two years in different ways: the first group with NK603 grains of corn genetically modified and the pesticide Roundup, the second with the GMO, but without the pesticide, the third party without GMOs, but with the pesticide, and the fourth without GMOs or pesticides. The results showed a high mortality rate of the first three groups due to high incidence of cancer.
